Numerical simulations of GRB jets from the BH horizon to post-breakout in collapsing stars

Monday, 5 May 2025 17:15 (15 minutes)

GRBs from collapsars have been studied by imposing jets at intermediate scales beyond the iron core region while exploring a wide range of parameters, such as luminosity and central engine duration. However, these conditions should be validated by studying jets launched directly from the central engine to show a global picture of the jet propagation inside and outside of the progenitor star. In this talk, I will present two dimensional GRMHD simulations of GRB jets launched from a black hole and followed through to breakout from the collapsing star. From our simulations, I will discuss the implications of the inner progenitor structure and magnetization on the properties of the jet emission (launching, duration, structure, and the variability).
