## A large facility for photosensors test at cryogenic temperature

Thursday, 22 September 2022 12:10 (15 minutes)

Silicon based photo-detectors are innovative light collecting devices and represent a successful technology in the field of direct dark matter search detectors based on liquified noble gases.

The DarkSide collaboration started a dedicated development and customization of SiPM technology for its specific needs resulting in the design, production and assembly of a large surface module of  $20x20 \text{ cm}^2$  to be used as PhotoDetectionUnit (PDU) in the DarkSide-20k experiment.

Production of a large number of such devices, as needed to cover about 15 m<sup>2</sup> of active surface inside the DarkSide-20k detector, requires a robust testing and validation process.

In order to match this requirement a dedicated test facility for the PDU tests was designed, integrated and commissioned at INFN Naples laboratory. The first commissioning test was successfully performed in 2021. Since then a number of testing campaigns were performed.

Results of these tests as well as a detailed description of the facility will be presented and discussed. Possible upgrades on the system will be also reported.

**Primary authors:** Dr CANCI, Nicola (Istituto Nazionale di Fisica Nucleare); Prof. DI CAPUA, Francesco (Università di Napoli Federico II and Istituto Nazionale di Fisica Nucleare); Prof. FIORILLO, Giuliana (Università Federico II di Napoli and Istituto Nazionale di Fisica Nucleare); Dr GRAUSO, Gianfrancesco (Istituto Nazionale di Fisica Nucleare); Prof. SUVOROV, Yury (Università Federico II and Istituto Nazionale di Fisica Nucleare)

Presenter: Dr CANCI, Nicola (Istituto Nazionale di Fisica Nucleare)

Session Classification: Photosensors

Track Classification: Light/charge readout (PMT, SiPM, WLS, electronics etc.)
